Two Span Capacities (one section over continuous support) Gravity Loading	PL-40
Two Span Capacities (one section over continuous support) Uplift Loading	PL-41

Purlin Load Tables

Notes

- Properties were computed in accordance with the 2001 edition of the AISI specifications, ASD provisions. When selecting sections for specific applications, applying additional checks may be required. Responsibility for designing and specifying materials for building and building components to comply with applicable state and local codes and specifications and safety considerations is with the designer and/or material specifier.
- For special conditions not covered in the tables, or for selecting sections for a specific application, contact your supplier.
- A yield point of 57 ksi (Fy) was used in determining the values in these tables.

Symbols

Ae	in.^2	Effective area of the section for axial loading
Area	in.^2	Full unreduced cross-section area of the section
B	in.	Flange width
B1	in.	Top flange width of non-symmetrical section
B2	in.	Bottom flange width of non-symmetrical section
Cw	in.^6	Torsional warping constant of the cross-section
D	in.	Depth of section
d	in.	Lip length
Ix	in.^4	Moment of inertia about the x-axis
Ixd	in. ^4	Deflection moment of inertia about the x-axis
Ixy	in.^4	Product of inertia of full section about major and minor centroidal axes
Iy	in.^4	Moment of inertia about the y-axis
J	in.^4	St. Venant torsion constant
KLx	ft.	Effective length for buckling about the x-axis
M	kip-in.	Allowable bending strength under simultaneous shear or axial load
Ma	kip-in.	Allowable bending strength
Ptf	kips	Allowable compressive axial strength for through-fastened condition
R	in.	Inside bend radius
rx	in.	Radius of gyration of the full cross-section about the x-axis
ry	in.	Radius of gyration of the full cross-section about the y-axis
Se	in.^3	Elastic section modulus of the effective section calculated with extreme compression or tension fiber at Fy (yield point)
Se Pos	in.^3	Elastic section modulus of the effective section calculated with extreme compression or tension fiber at Fy (yield point), for positive bending
Se Neg	in.^3	Elastic section modulus of the effective section calculated with extreme compression or tension fiber at Fy (yield point) for negative bending
Sx	in.^3	Section modulus for the full section (x-axis)
Sy	in.^3	Section modulus for the full section (y-axis)
V	kips	Allowable shear strength under simultaneous bending load
Va	kips	Allowable shear strength
Wt/ft	lb	Weight of section, in pounds per foot of length
x bar	in.	Distance from extreme fiber to the neutral axis along the x-axis
x0	in.	Distance from the shear center to centroid along the principal x-axis
y bar	in.	Distance from the extreme fiber to the neutral axis along the y-axis

Purlin Load Tables

Notes

Torsional Properties

1. These properties are used to compute the laterally braced strength of sections. (Reference AISI c3.1.2)

Bending and Axial Properties

1. Effective section modulus S_e is computed using effective widths of elements. (Reference AISI B2, B3 and B4).
2. P_{tf} is the compressive axial strength for section having one flange attached to a qualifying deck or sheathing with qualifying fasteners. (Reference AISI C4.6)
3. Appropriate factors of safety have been applied.

Combined and Shear Bending

1. Listed values are the allowable combined shear and bending in the absence of axial load.
2. For a section to qualify, the applied shear force and bending must each be no greater than the values for a paired V and M in the table.
3. Appropriate factors of safety have been applied.
4. Allowable values were computed assuming the use of plates or clips at supports which will effectively transfer loads directly to the web of the member. If sections are to bear directly on the supports, the shear force must not exceed the allowable web crippling value and the section must be checked for crippling/bending interaction.
5. Allowable values listed in the "Unbraced" columns are for cases where no lateral bracing of any type is present for the full span length.
6. Allowable values listed in the "Through-Fastened" columns are for cases where the tension flange is through-fastened to deck or sheathing and the compression flange is unbraced. Allowable values for sections not qualifying for the through-fastened geometric requirements are listed as zero. Allowable values for sections meeting some of the geometric requirements of AISI 2001 Section C3.1.3 but failing others by a narrow margin are listed with an asterisk (*) next to the value (please see the through fastened qualification table). It is up to the engineer of record to decide whether or not the allowable values for partially qualifying sections may be utilized for a given project. The additional requirements of AISI 2001 Section C3.1.3 regarding support conditions, panel type, allowable insulation thickness, and panel fasteners must be met in order to utilize the listed values.

Purlin Load Tables

Notes

Web Crippling

1. One-flange loading or reaction occurs when the clear distance between the bearing edges of adjacent opposite concentrated loads or reactions is greater than 1.5 times the flat dimension of the section's web depth.
2. Two-flange loading or reaction occurs when the clear distance between the bearing edges of adjacent opposite concentrated loads or reactions is equal to or less than 1.5 times the flat dimension of the section's web depth
3. End loading or reaction occurs when the distance from the edge of the bearing to the end of the member is equal to or less than 1.5 times the flat dimension of the section's web depth.
4. Interior loading or reaction typically occurs when the distance from the edge of the bearing to the end of the member is greater than 1.5 times the flat dimension of the section's web depth.
5. Appropriate factors of safety have been applied.

Axial Capacities

1. Axial capacities are allowable concentric loads (kips) in the absence of bending moment.
2. Axial capacities are for sections supported laterally at the distances specified in the table. Axial capacities in the column labeled "Unbraced" are for sections without any lateral supports.
3. Distance between major axis supports must not exceed KLx.
4. Appropriate factors of safety have been applied.
5. Consult General Information for definitions of symbols used in these tables.

Purlin Load Tables

Notes

Simple Span Capacities

1. Capacities are total uniformly distributed load which can be supported by the section in the absence of axial load. The weight of the section has not been subtracted from these values.
2. Capacities listed in the "Fully Braced" column are the allowable load for cases where the compression flange is fully braced laterally (gravity load capacity for top flange fully braced or for through-fastened; uplift capacity for bottom flange fully braced).
3. Capacities listed in the "Laterally Braced" column are the allowable load for cases where the compression flange is laterally braced at intermediate points (gravity capacity for top flange laterally braced; uplift capacity for bottom flange laterally braced). The distance between lateral supports (L_y) utilized for determining the capacities is:

Distance Between Lateral Supports			
Section Depth 3" – 6"		Section Depth 8" – 14"	
Span (ft) L	y (in)	Span (ft) L	y (in)
8	48 1	5	60
10 6	0 2	0 8	0
12 7	2	25	75
15 6	0 3	0	72

4. Capacities listed in the "Through-Fastened" column are the allowable load for cases where one flange is through-fastened to deck or sheathing and the opposite flange is unbraced (uplift capacity for top flange through-fastened). Capacities for sections not qualifying for the through-fastened geometric requirements are listed as "N/A". Capacities for sections meeting some of the geometric requirements of AISI 2001 Section C3.1.3 but failing others by a narrow margin are listed with an asterisk (*) next to the value (please see the through-fastened qualification table). It is up to the engineer of record to decide whether or not the capacities for partially qualifying sections may be utilized for a given project. The additional requirements of AISI 2001 Section C3.1.3 regarding support conditions, panel type, allowable insulation thickness, and panel fasteners must be met in order to utilize the listed capacities.
5. Capacities listed in the "Unbraced" column are the allowable load for cases where the compression flange has no lateral braces (gravity capacity for top flange completely unbraced; uplift capacity for bottom flange completely unbraced without a through-fastened top flange).
6. Appropriate factors of safety have been applied.
7. Capacities were computed assuming the use of plates or clips at supports which will effectively transfer loads directly to the web of the member. If sections are to bear directly on the supports, the sections must be checked for web crippling.
8. Deflection values are the amount of deflection that occurs when the full allowable load is applied. For applications with special deflection requirements, it may be necessary to adjust the allowable capacities.
9. Consult General Information for definitions of symbols used in these tables.

Purlin Load Tables

Notes

Continuously Braced Outside Flange, Laterally Braced Inside Flange Capacities

1. Capacities are total uniformly distributed load which can be supported by the section in the absence of axial load. The weight of the section has not been subtracted from these values.
2. Capacities are for sections supported laterally at the top flange for their full length and at a distance no greater than Ly for the bottom flange. In the region between the interior support and the inflection point, the bending strength for gravity loading is computed using a lateral brace distance equal to the smaller of Ly and the distance from the support to the inflection point.
3. Appropriate factors of safety have been applied.
4. Capacities are computed assuming the sections are continuous over the designated number of spans, with laps as specified at all interior supports. The lap length given is the total length of the lapped region at each interior support. The same lap length is used at all interior supports.
5. Deflection values are the amount of deflection that occurs when the full allowable load is applied. For applications with special deflection requirements, it may be necessary to adjust the allowable capacities.
6. Capacities were computed assuming the use of plates or clips at supports which will effectively transfer loads directly to the web of the member. If sections are to bear directly on the supports, the sections must be checked for web crippling at all supports and for crippling/bending interaction at interior supports.
7. Consult General Information for definitions of symbols used in these tables.

Laterally Braced both Flanges Capacities

1. Capacities are total uniformly distributed load which can be supported by the section in the absence of axial load. The weight of the section has not been subtracted from these values.
2. Capacities are for sections supported laterally at both flanges at a distance no greater than Ly. In the region between the interior support and the inflection point, the bending strength for gravity loading is computed using a lateral brace distance equal to the smaller of Ly and the distance from the support to the inflection point.
3. Appropriate factors of safety have been applied.
4. Capacities are computed assuming the sections are continuous over the designated number of spans, with laps as specified at all interior supports. The lap length given is the total length of the lapped region at each interior support. The same lap length is used at all interior supports.
5. Deflection values are the amount of deflection that occurs when the full allowable load is applied. For applications with special deflection requirements, it may be necessary to adjust the allowable capacities.

Purlin Load Tables

Notes

Laterally Braced both Flanges Capacities (continued)

6. Capacities were computed assuming the use of plates or clips at supports which will effectively transfer loads directly to the web of the member. If sections are to bear directly on the supports, the sections must be checked for web crippling at all supports and for crippling/bending interaction at interior supports.
7. Consult General Information for definitions of symbols used in these tables.

Through-Fastened Capacities (Qualifying and Partially Qualifying)

1. Capacities are total uniformly distributed load which can be supported by the section in the absence of axial load. The weight of the section has not been subtracted from these values.
2. Sections listed as "Section Qualifies" fully meet the geometric requirements of AISI 2001 Section C3.1.3. Sections listed as "Section Partially Qualifies" meet some of the geometric requirements of AISI 2001 Section C3.1.3 but fail others by a narrow margin (please see the through-fastened qualification table). It is up to the engineer of record to decide whether or not the capacities for partially qualifying sections may be utilized for a given project.
3. The additional requirements of AISI 2001 Section C3.1.3 regarding support conditions, panel type, allowable insulation thickness, and panel fasteners must be met in order to utilize the listed capacities.
4. Capacities are for sections with the top flange through-fastened to deck or sheathing and no lateral bracing for the bottom flange. In the region between the end of the lap and the inflection point, the bending strength for gravity loading is computed using a lateral brace distance equal the distance from the end of the lap to the inflection point. The lapped region is considered to be continuously braced at both flanges.
5. Appropriate factors of safety have been applied.
6. Capacities are computed assuming the sections are continuous over the designated number of spans, with laps as specified at all interior supports. The lap length given is the total length of the lapped region at each interior support. The same lap length is used at all interior supports.
7. Deflection values are the amount of deflection that occurs when the full allowable load is applied. For applications with special deflection requirements, it may be necessary to adjust the allowable capacities.
8. Capacities were computed assuming the use of plates or clips at supports which will effectively transfer loads directly to the web of the member. If sections are to bear directly on the supports, the sections must be checked for web crippling at all supports and for crippling/bending interaction at interior supports. Please note that AISI 2001 Section C3.1.3 requires that both flanges be prevented from moving laterally at the supports.
9. Consult General Information for definitions of symbols used in these tables.

Purlin Load Tables

Notes

One Section Continuous over Supports Capacities

1. Capacities are total uniformly distributed load which can be supported by the section in the absence of axial load. The weight of the section has not been subtracted from these values.
2. Capacities are computed assuming a single section continuous over the designated number of spans.
3. Capacities listed in the "Fully Braced" column are the allowable load for sections supported laterally at both flanges for their full length.
4. Capacities listed in the "Fully Braced / Laterally Braced" column are the allowable load for sections supported laterally at the top flange for their full length and at a distance no greater than Ly for the bottom flange. In the region between the interior support and the inflection point, the bending strength for gravity loading is computed using a lateral brace distance equal to the smaller of Ly and the distance from the support to the inflection point. The distance between lateral supports (Ly) utilized for determining the capacities is:

Distance Between Lateral Supports	
Span (ft) L	y (in)
8	48
10	60
12	72
15	60

5. Capacities listed in the "Through-Fastened" column are the allowable load for cases where one flange is through-fastened to deck or sheathing and the opposite flange is unbraced. In the region between the interior support and the inflection point, the bending strength for gravity loading is computed using a lateral brace distance equal to the distance from the support to the inflection point. Capacities for sections not qualifying for the through-fastened geometric requirements are listed as zero. Capacities for sections meeting some of the geometric requirements of AISI 2001 Section C3.1.3 but failing others by a narrow margin are listed with an asterisk (*) next to the value (please see the through-fastened qualification table). It is up to the engineer of record to decide whether or not the capacities for partially qualifying sections may be utilized for a given project. The additional requirements of AISI 2001 Section C3.1.3 regarding support conditions, panel type, allowable insulation thickness, and panel fasteners must be met in order to utilize the listed capacities.
6. Capacities listed in the "Unbraced" column are the allowable load for cases where no lateral bracing of any type is present for either flange for the full span length.
7. Appropriate factors of safety have been applied.
8. Deflection values are the amount of deflection that occurs when the full allowable load is applied. For applications with special deflection requirements, it may be necessary to adjust the allowable capacities.

Notes:

1. It is up to the engineer of record to decide whether or not the capacities for partially qualifying sections may be utilized for a given project.
2. The additional requirements of AISI 2001 Section C3.1.3 regarding support conditions, panel type, allowable insulation thickness, and panel fasteners must also be met.
3. Y = section meets all geometric constraints
P = section fails one or more geometric constraints but is within 10% of qualifying
N = section fails one or more geometric constraints by more than 10%
4. All conditions reference AISI 2001 Section C3.1.3 pages 65-66.

1. Capacities are total uniformly distributed loads without axial loading

2. The weight of the section HAS been subtracted from the loads

3. All published loads are allowable and have the AISI appropriate safety factors.

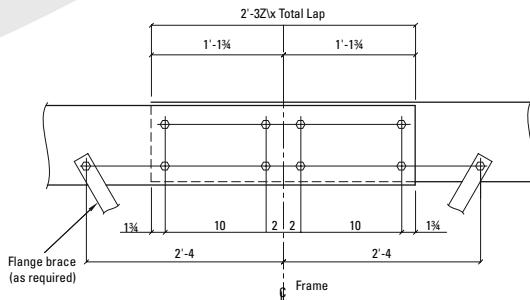

4. If the sections bear directly on the supports, without any web clips or plates, then the section must be checked for web crippling

1. Capacities are total uniformly distributed loads without axial loading

2. The weight of the section HAS been subtracted from the loads

3. All published loads are allowable and have the AISI appropriate safety factors.

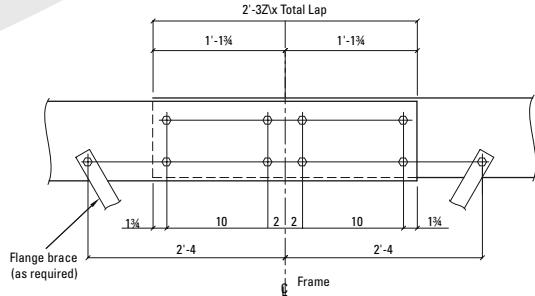

4. If the sections bear directly on the supports, without any web clips or plates, then the section must be checked for web crippling

1. Capacities are total uniformly distributed loads without axial loading

2. The weight of the section HAS been subtracted from the loads

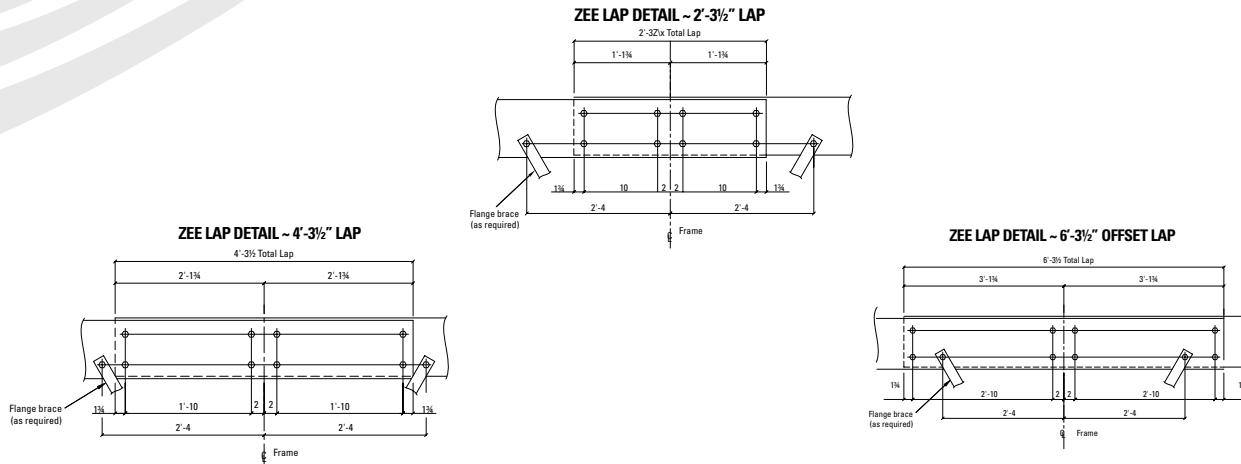

3. All published loads are allowable and have the AISI appropriate safety factors.

4. If the sections bear directly on the supports, without any web clips or plates, then the section must be checked for web crippling

1. Capacities are total uniformly distributed loads without axial loading

2. The weight of the section HAS been subtracted from the loads

3. All published loads are allowable and have the AISI appropriate safety factors.

4. If the sections bear directly on the supports, without any web clips or plates, then the section must be checked for web crippling
