

ZIRCON ANNUAL REVIEW *SAMPLE*

NEW EDITION TO BE RELEASED Q2 2014

PROPOSED TABLE OF CONTENTS*

EXECUTIVE SUMMARY

1.0: INTRODUCTION AND ZIRCON MARKET

- 1.1 Introduction
- 1.2 The global zircon market
- 1.3 Overview of zircon end-uses
- 1.4 Structure of report
- 1.5 Confidentiality and disclaimer

2.0: END-USES: CERAMICS AND SANITARYWARE

- 2.1 Introduction
- 2.2 Production of ceramic tiles
- 2.3 Zircon in ceramic tiles
- 2.4 Manufacture of sanitaryware
- 2.5 Segment developments in 2013

3.0: END-USES: SPECIALTY CHEMICALS AND MATERIALS

- 3.1 Introduction
- 3.2 Zirconium chemicals
- 3.3 Zirconia
- 3.4 Zirconium metal
- 3.5 Segment developments in 2013

4.0: END-USES: REFRACTORIES AND FOUNDRIES

- 4.1 Introduction
- 4.2 Refractories
- 4.3 Foundries and casting
- 4.4 Segment developments in 2013

5.0: ZIRCON SUPPLY

- 5.1 Introduction
- 5.2 Zircon supply in 2013
- 5.3 Zircon supply by region
- 5.4 Key zircon producers

6.0: ZIRCON DEMAND DYNAMICS

- 6.1 Overview – substitution and thrifting
- 6.2 Zircon demand by region
- 6.3 Demand drivers
- 6.4 Zircon demand by market
- 6.5 Zircon trade in 2013
- 6.6 Zircon demand outlook to 2014

7.0: ZIRCON PRICING

- 7.1 Price forecasting methodology
- 7.2 Overview of 2013
- 7.3 Trade
- 7.4 Pricing outlook to 2015

8.0: NEW PROJECTS

- 8.1 New supply
- 8.2 New projects

9.0: STRATEGIC ISSUES AND OUTLOOK

APPENDIX 1 - PRODUCER PROFILES

APPENDIX 2 - CONSUMER PROFILES

APPENDIX 3 – NEW PROJECTS PROFILES

* minor changes may be made to this outline prior to publication

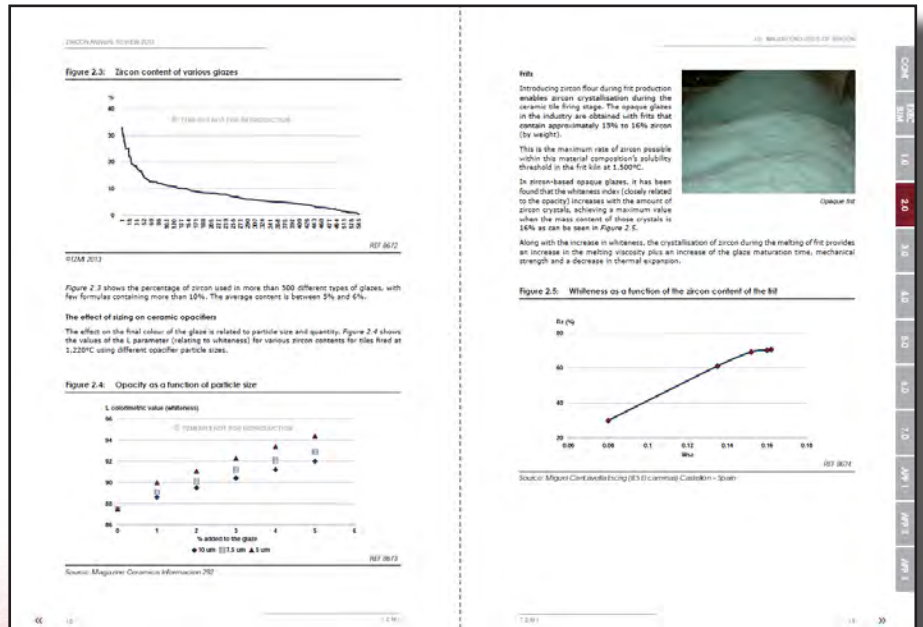

SAMPLE OF 2013 EDITION

NEW EDITION TO BE RELEASED Q2 2014

THE ZIRCON MARKET AND MAJOR END-USES

Comprehensive analysis of the major end-uses for zircon

Sections for each end-use with an examination of demand drivers

DEMAND DYNAMICS

Demand broken down by regions, drivers, growth in end-uses.

Figure 3.10: Zircon consumption in foundries by region in 2012

Table 3.4: Regional zircon consumption in foundries: 2010-2014

Region	2010	2011	2012	2013	2014
Europe	33	33	28	28	28
North America	30	30	34	34	35
Japan	3	2	4	4	4
China	25	29	21	25	29
Other Asia Pacific	31	29	21	21	22
Other countries	5	5	5	5	5
Total	136	137	112	116	119

The of zircon sand in foundry
Zircon is used in both sand casting and investment casting, although the latter method uses more zircon due to the typically greater intricacy of the finished work piece. Figure 3.11 describes the use of zircon in both methods.
Sand casting requires low thermal expansion. When casting temperatures exceed 800°C there is a noticeable difference between the dimensional performance of zircon and silica and beyond 1,000°C zirconite also begins to expand. For the same reason, zircon is a preferred material in the shell moulds used for investment casting. Low reactivity with other metals and non-setting are also properties of zircon.
Recent technological trends are optimising the amount of zircon consumed in casting. A foundry in the UK, Sheffield Foundry, has developed a way of optimising core coatings so as not to melt zircon slugs. Meanwhile, in China it is reported that foundries are using thinner zircon core coatings.

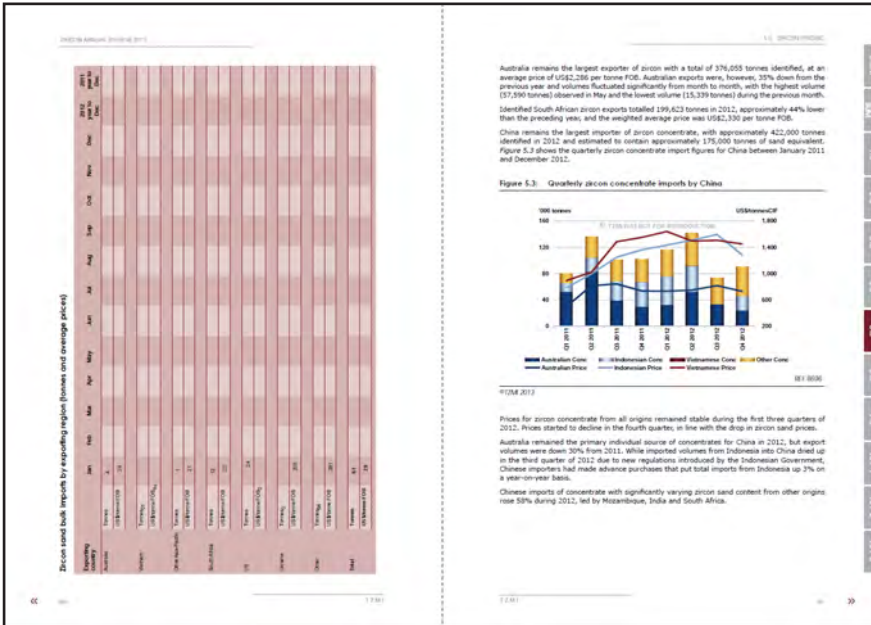

Table 3.7: Metal casting industry in 2011

Country	Million tonnes	Planes
China	41.5	30,000
USA	16.33	2,000
India	9.99	4,500
Germany	5.47	612
Japan	4.75	1,812
Russia	4.2	1,500
Spain	3.34	1,325
Korea	2.34	890
Katy	2.21	1,111
France	2.05	441

Figure 3.11: Casting end-use markets in 2011

SUPPLY AND PRICING

Examines supply developments in the past year.

Pricing information targets trends by producer and region.

“ Regionally, Australia remains the largest zircon producing country, accounting for 36% of global production in 2012. ”

Trade analysis across the globe

China's influence on the zircon market

Export trade analysis by country

NEW PROJECTS

Table 4.1: Pipeline of new projects

Project	Country	Company	Additional capacity		Earliest start-up
			100 tpa	1000 tonnes zircon pa	
Approved projects not yet commissioned					
Kwale	Kenya	Base Resources	246	40	Q4 2013
Mama - Stage 2	Mozambique	Kemman Resources	250	30	2013
Gangama dry mining	Sierra Leone	Sierra Rutile Ltd	107	10	2014
Grande Côte	Seychelles	TIC Limited	350	80	Q1 2014
Palatona	South Africa	Tonka	190	80	2015
			1,113	220	
Projects with completed technical feasibility studies					
Colum Zircon	Australia	Gurcon Resources	56	40	2015-16

Moolenaar and Nibart	Mozambique	Pathfinder Minerals			
Pulaman	Sri Lanka	PKZ Resources			
North Perth Basin	Australia	Shelford Resources			
Altabasca Sands	Canada	Titanium Corp			
Total projects not yet commissioned			2,047	584	

4.2 Approved projects not yet commissioned

Base Resources - Kwale, Kenya

Base Resources' Kwale deposit is approximately 40 km south of the port city of Mombasa. The property, which is 12 km inland, contains proven reserves of 86.2 million tonnes at 5.4% HM and probable reserves of 54.4 million tonnes at 4.0% HM, based on two of the three known deposits (the Central and South Dune areas). Once production has commenced, a second phase of development is targeted for the North Dune deposit and several other coastal deposits.

Expected production for the first six years of operation is 330,000 tpa of sulfate ilmenite, 75,000 tpa of rutile and 40,000 tpa of zircon. An updated and enhanced feasibility study was completed in the second quarter of 2011, with shafts and financing arrangements completed in the second half of 2011. With a total mine life of 11 years, the Kwale project is currently under construction and commissioning is targeted at Q3 2013 and first shipment in Q4 2013.

Kemman Resources - Momo Stage 2, Mozambique

At full capacity, the Momo project is capable of producing 800,000 tpa of ilmenite, 14,000 tpa of rutile and 50,000 tpa of zircon. In 2010, Kemman announced a planned expansion to improve the current capacity levels by 50%, increasing annual production to 1.2 million tonnes of ilmenite, 22,000 tonnes of rutile and 60,000 tonnes of zircon.

Construction for the Stage 2 expansion commenced in February 2011 and involves a new dredge pond and a third dredge, as well as upgrades to existing trenches and plants. The company recently announced that commissioning was under way with full production expected later in 2013.

Sierra Rutile Ltd - Gangama Dry Mining, Sierra Leone

Sierra Rutile Ltd (SRL) announced in October 2012 the approval of the development of the Gangama dry mining project. The Gangama dry mining project will replace the small Molybdenum tailings dredge as SRL's next expansion project. The concept involves the excavation of SRL's Gangama deposit using conventional earth moving equipment, followed by the initial processing of the ore in a wet concentrator located at Gangama before being fed to the existing MSP for processing into final products.

With an estimated resource of 40 million tonnes at an average grade of 4.69% HM, the 1,000 tpd dry mining operation is projected to produce 83,400 tpa of rutile, 46,000 tpa of chloride ilmenite and 9,500 tpa of zircon concentrate over a mine-life of six years. With a construction lead time of 12 months, the Gangama dry mining project is expected to start up in 2014.

The company reported in early 2013 that pre-construction activities have begun on site, including dam construction for process water storage, draining of the Gangama dredge pond as well as upgrading of access roads.

Key personnel Jean-François Turgeon – Acting Managing Director
Denis Booysen – General Manager, Engineering
Fundi Dlamini – General Manager, Communities and Corporate Relations
Bheki Gumbi – General Manager, Human Resources
Joey Kunji-Behari – General Manager, Smelting and Processing
Johan Jacobs – General Manager, Technical

Background In 1971, the Industrial Development Corporation began a detailed investigation of the Richards Bay area. A Canadian producer of titania slag (QIT) was also looking for major ilmenite deposits in 1974. These two organisations, together with Union Corporation (later Gencor now BHP Billiton), formed RBM in 1976 to mine and beneficiate the vast mineral-rich sands in the coastal dunes that extend 17 km in a two kilometre wide strip from just north of Richards Bay. In 1985 the company acquired the mining rights to additional ore reserves both north and south of the original deposit.

During 2001, RBM started dry mining operations to supplement its dredge mining operations.

Legislation passed by the South African Government in 2004 requires that mining companies sell 26% of their mines to black investors by 2014. The company announced in December 2008 that a definitive agreement with a Broad Based Black Economic Empowerment (BBBEE) consortium, Blue Horizon, had been signed. In December 2009, the rand 4.5 billion (US\$55.4 million) deal was completed. Blue Horizon acquired a 24% equity interest in RBM, with 2% of the equity held by permanent employees through an employee participation scheme. It is the largest broad-based black economic empowerment deal in the region to date.

In July 2008, the company announced that it had approved more than rand 1 billion (US\$147.2 million) in funding for a new MSP tailings treatment plant project. The project is expected to extend mine life by a further five years. RBM also announced plans to generate sufficient electricity in-house to be able to supply a portion of the power plants requirements; approximately 6.5 MW by 2011.

Following the completion of the BBBEE deal, Richards Bay Minerals (RBM) consists of two separate operating companies; Richards Bay Mining (Pty) Ltd, which is responsible for mining operations; and Richards Bay Titanium (Pty) Ltd, which is responsible for the smelting and beneficiation process

In April 2009, Rio Tinto removed one of the four furnaces at Richards Bay from operation for a period of five months for a planned rebuild. >>

Richards Bay Minerals

Operations << RBM mines dunal sand deposits in KwaZulu-Natal, South Africa, stretching from 10 to 50 km north of Richards Bay. Four separate mining plants provide a combined mining capacity of approximately 115 million tpa. The most recent mining plant consists of two dredges and one concentrator, and was commissioned at the end of 1999. It was designed to compensate for falling ore grades. Auxiliary dry mining is also employed at RBM, and now contributes an estimated 15% of the total volume of ore mined. Much of the dry mined ore is sourced from areas inaccessible to the dredges used as the principal mining method.

Mineral concentrate is trucked to a central processing plant where ilmenite is extracted by magnetic separation and the non-magnetics are further processed for the recovery of zircon and rutile. The mineral processing plant currently has capacity to produce up to 240,000 tpa of zircon and 90,000 tpa of rutile. Up to 160,000 tpa of zircon are acid leached to produce a 'premium' grade zircon.

In its current leases to the north of Richards Bay, and in an additional lease south of Richards Bay, it is understood that RBM has reserves sufficient for more than 20 years operation at current mining rates. Present measured reserves (expressed in terms of slag product) stand at 24.9 million tonnes, with a further 3.0 indicated and inferred million tonnes categorised as resources.

RBM announced in March 2011 that it intended to mine its Zulti South mining lease area, south of Richards Bay, extending mining operations to around 2043. Mining of the area could start as early as 2016.

In March 2011, the company commissioned its tailings treatment plant and began production in April 2011. RBM plans to treat 2.2 million tonnes of tailings per year.

Recent developments In February 2012, BHP Billiton Ltd agreed to sell its 37% stake in RBM to Rio Tinto.

In February 2013, Rio Tinto announced that it was taking action at a number of its operations and would place its zircon and rutile processing operations at RBM on care and maintenance, while maintaining production at the core ilmenite mining and smelting operations. The decision followed the announcement of Rio Tinto's annual results for 2012. Rio Tinto reported a US\$3 billion loss for the 2012 year, citing a US\$14.4 billion write down relating to aluminium businesses and coal assets in Mozambique.

Structure of the zirconia, zirconium chemicals and metal industries

© TZMI 2013

Zircon is used in the sanitaryware industry to provide opacity and whiteness. Zircon only forms part of the sanitaryware glaze and rarely is in the ceramic structure of the sanitaryware body. The typical content of zircon in a sanitaryware glaze is between 15-16%.

Specialty chemicals and materials

Zirconium chemicals comprise a varied group, each member containing zirconium as an active constituent. The most common intermediate product, from which many of the others are manufactured, is zirconium oxychloride octohydrate or ZOC, which has the formula, $ZrOCl_2 \cdot 8H_2O$.

Another often-used intermediate is zirconium basic sulfate, known as ZBS.

While they have significantly different end-uses, the two general types of zirconia - fused and chemical - share a range of characteristics which make them valuable materials in various specialist applications. The principal differences between the two types of zirconia are:

- Chemical zirconia is considerably purer than fused zirconia, so it tends to be used in the applications which require greater precision of performance:
- The surface area to weight ratio of the crystals of chemical zirconia is far higher.

Refractories and foundries

Zircon has a high melting point and high resistance to thermal shock, making it a suitable candidate for use as a refractory in high-temperature applications. Zirconia, exhibits very similar refractory properties to zircon, except that it has a higher melting point and can be used in applications where temperatures exceed 1,990°C.

The main advantage of zircon as a foundry sand is its refractoriness and resistance to metal penetration as well as its ability to withstand high temperatures for long periods. This allows zircon to be used in foundries for the casting of high-alloy stainless steels, at temperatures as high as 1,650°C.

The combination of these characteristics (refractoriness, low thermal expansion and chemical stability), make zircon an ideal non-silica foundry sand. High prices however, mean it is used only in high-end castings and specialised applications.

Zircon supply

Global zircon supply grew by 23% in 2010 from 2009 levels, reaching 1.3 million tonnes and reached 1.6 million tonnes in 2011 amid escalating prices. The price of zircon sand experienced a sharp correction during 2012. Prolonged economic malaise in Europe and overstocking in China were cited as the primary causes, as well as the perennial price increases with which customers on both continents had to contend.

In light of the worsened market conditions, 2012 witnessed no new projects and the reduction of output and mothballing of several others. Investment continues, however, and additional supply in 2014, 2015 and 2016 can be expected.

Regionally, Australia remains the largest zircon producing country, accounting for approximately 36% of global zircon output. The following figure shows the distribution of zircon production by country in 2012.

South Africa is the second largest zircon producing country, accounting for 30% of global production in 2012. China is also fast becoming a key zircon producing country. Accounting for 15% of global output, China's zircon demand is now the largest in the world as imports 80% of its zircon.

Iluka remains the largest single producer of zircon, accounting for around 30% of global zircon output since 2001 or around 300,000 tonnes. Richards Bay Minerals is the next largest zircon producer, with estimated annual output of 270,000 tonnes in 2012, followed by China with 205,000 tonnes.

Distribution of global zircon production by country in 2012

TZMI - 2014 PUBLICATION SUITE

TZMI publications provide a comprehensive range of authoritative data and informed commentary on all aspects of the titanium minerals, zircon and TiO₂ industries. Full time research staff are engaged in the collection, analysis and distribution of data. A comprehensive database is maintained including regularly updated supply and demand models and operating cost data for all major producers.
